THIS QUALITY INSPECTED &

## SHIP STRUCTURE COMMITTEE

The SHIP STRUCTURE COMMITTEE is constituted to prosecute a research program to improve the hull structures of ships and other marine structures by an extension of knowledge pertaining to design, materials, and methods of construction.

|                                                                                                                                 |                                                                                                                                   |                                                                                                |

### EXECUTIVE DIRECTOR

CDR Stephen E. Sharpe, USCG  
U. S. Coast Guard

### CONTRACTING OFFICER TECHNICAL REPRESENTATIVE

Mr. William J. Siekierka  
Naval Sea Systems Command

## SHIP STRUCTURE SUBCOMMITTEE

The SHIP STRUCTURE SUBCOMMITTEE acts for the Ship Structure Committee on technical matters by providing technical coordination for determining the goals and objectives of the program and by evaluating and interpreting the results in terms of structural design, construction, and operation.

### MILITARY SEALIFT COMMAND

Mr. Robert E. Van Jones (Chairman)  
Mr. Rickard A. Anderson  
Mr. Michael W. Touma  
Mr. Jeffrey E. Beach

### MARITIME ADMINISTRATION

Mr. Frederick Seibold  
Mr. Norman O. Hammer  
Mr. Chao H. Lin  
Dr. Walter M. Maclean

### U. S. COAST GUARD

CAPT G. D. Marsh  
CAPT W. E. Colburn, Jr.  
Mr. Rubin Scheinberg  
Mr. H. Paul Cojeen

### AMERICAN BUREAU OF SHIPPING

Mr. Stephen G. Arntson  
Mr. John F. Conlon  
Mr. Phillip G. Rynn  
Mr. William Hanzelek

### NAVAL SEA SYSTEMS COMMAND

Mr. W. Thomas Packard  
Mr. Charles L. Null  
Mr. Edward Kadala  
Mr. Allen H. Engle

### TRANSPORT CANADA

Mr. John Grinstead  
Mr. Ian Bayly  
Mr. David L. Stocks  
Mr. Peter Timonin

### DEFENCE RESEARCH ESTABLISHMENT ATLANTIC

Dr. Neil Pegg  
LCDR D. O'Reilly  
Dr. Roger Hollingshead  
Mr. John Porter

## SHIP STRUCTURE SUBCOMMITTEE LIAISON MEMBERS

### U. S. COAST GUARD ACADEMY

LCDR Bruce R. Mustain

### U. S. MERCHANT MARINE ACADEMY

Dr. C. B. Kim

### U. S. NAVAL ACADEMY

Dr. Ramswar Bhattacharyya

### CANADA CENTRE FOR MINERALS AND ENERGY TECHNOLOGIES

Dr. William R. Tyson

### SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS

Dr. William Sandberg

### U. S. TECHNICAL ADVISORY GROUP TO THE INTERNATIONAL STANDARDS ORGANIZATION

CAPT Charles Piersall

### NATIONAL ACADEMY OF SCIENCES - MARINE BOARD

Dr. Robert Sielski

### NATIONAL ACADEMY OF SCIENCES - COMMITTEE ON MARINE STRUCTURES

Mr. Peter M. Palermo

### WELDING RESEARCH COUNCIL

Dr. Martin Prager

### AMERICAN IRON AND STEEL INSTITUTE

Mr. Alexander D. Wilson

### OFFICE OF NAVAL RESEARCH

Dr. Yapa D. S. Rajapaske

### STUDENT MEMBER

Mr. Trevor Butler  
Memorial University of Newfoundland

Member Agencies:

American Bureau of Shipping  
Defence Research Establishment Atlantic  
Maritime Administration  
Military Sealift Command  
Naval Sea Systems Command  
Transport Canada  
United States Coast Guard

**IMPROVED SHIP HULL DETAILS RELATIVE TO FATIGUE**

As margins for operating ships get tighter and the costs for failures rise exponentially the need to prevent fractures at the design stage becomes increasingly more critical. This report provides one more tool for the designer to use. It presents a fatigue design methodology that applies existing fatigue data to welded ship details. A variation of the nominal stress approach is used for weld terminations in attached bracket details. This helps in selecting the weld configurations that improve fatigue life and assesses the impact of geometric stress concentration factors and combined loadings that are typical of welded ship structural details. Case studies are shown to demonstrate the methodology. A glossary of terms used is provided and recommendations are presented for future research.

J. C. CARD

Rear Admiral, U.S. Coast Guard  
Chairman, Ship Structure Committee

| 16. Abstract<br><br>This report presents a fatigue design strategy for welded ship structural details. The fatigue design strategy is based on cumulative damage theory using nominal stress. The approach is modified to account for the complex geometry of welded ship structural details. Fatigue notch factors and stress concentration factors are derived from experimental data and finite element analysis. Guidance is provided showing detail designers how to improve the fatigue life of details using this approach. |                                                          |                                                                                                                                                                         |                                               |

## LIST OF SYMBOLS

|                     |   |                                                                                                                                         |
|---------------------|---|-----------------------------------------------------------------------------------------------------------------------------------------|
| $a$                 | = | Bracket leg length                                                                                                                      |
| $b$                 | = | Fatigue strength exponent                                                                                                               |
| BM                  | = | Base Metal                                                                                                                              |
| $C$                 | = | Constant relating to the mean S-N curve                                                                                                 |
| $D$                 | = | Depth of structural member                                                                                                              |
| HAZ                 | = | Heat affected zone                                                                                                                      |
| $K_f$               | = | Fatigue notch factor                                                                                                                    |
| $K_{f_{weld}}$      | = | Fatigue notch factor for weldment                                                                                                       |
| $K_{f_{max}}^A$     | = | Value of $K_f$ for axial component of applied stress                                                                                    |
| $K_{f_{max}}^B$     | = | Value of $K_f$ for bending component of applied stress                                                                                  |
| $K_{f_{max}}^{eff}$ | = | Value of $K_f$ representing combined effects of axial and bending stresses                                                              |
| $K_{scf}$           | = | Geometric Stress Concentration Factor                                                                                                   |
| $K_t$               | = | Elastic stress concentration factor                                                                                                     |
| $m$                 | = | Inverse slope of mean S-N regression line, also used as exponent controlling the thickness effect                                       |
| $N$                 | = | Number of cycles corresponding to a particular fatigue strength; total number of nominal stress range cycles also known as fatigue life |
| $n_i$               | = | Number of stress cycles in stress block $i$                                                                                             |
| $N_i$               | = | Number of cycles of failure at a constant stress range                                                                                  |
| $N_i$               | = | Life devoted to crack initiation and early growth                                                                                       |
| $N_p$               | = | Life devoted to fatigue crack propagation                                                                                               |
| $N_T$               | = | Total fatigue life                                                                                                                      |
| $R$                 | = | Ratio of minimum to maximum applied stress                                                                                              |
| $s$                 | = | Standard deviation                                                                                                                      |
| SD                  | = | Log standard deviation of fatigue strength at $10^6$ cycles                                                                             |
| $\Delta S_{pp}$     | = | Fatigue strength of a plain plate specimen at a given life ( $N_i$ )                                                                    |

## LIST OF SYMBOLS

(continued)

|                            |   |                                                                                                       |
|----------------------------|---|-------------------------------------------------------------------------------------------------------|
| $\Delta S_{\text{weld}}$   | = | Experimental fatigue strength range of a welded plate specimen at a given life ( $N_i$ )              |
| $\Delta S_R$               | = | Stress range                                                                                          |
| $S_{\text{ref}}$           | = | Design stress for the reference thickness                                                             |
| $S_a^A$                    | = | Axial component of applied stress                                                                     |
| $S_a^B$                    | = | Bending component of applied stress                                                                   |
| $S_a^T$                    | = | Applied mean stress                                                                                   |
| $S_u$                      | = | Ultimate strength                                                                                     |
| $S_y$                      | = | Yield strength                                                                                        |
| $t$                        | = | Plate thickness                                                                                       |
| WM                         | = | Weld metal                                                                                            |
| $V_s$                      | = | Variation due to uncertainty in equivalent stress range; includes effects of error in stress analysis |
| $x$                        | = | Ratio of applied bending to applied total stresses                                                    |
| $\alpha$                   | = | Geometry factor                                                                                       |
| $\beta$                    | = | Number of stress blocks                                                                               |
| $\Delta S_R$               | = | Design stress range                                                                                   |
| $\eta$                     | = | Limit damage ratio                                                                                    |
| $\sigma'_f$                | = | Fatigue strength coefficient                                                                          |
| $\sigma_r$                 | = | Local (notch root) residual stress                                                                    |
| $\sigma_B$                 | = | Bending stress                                                                                        |
| $\tau$                     | = | Shear Stress                                                                                          |
| $\sigma_f$                 | = | Fatigue design stress                                                                                 |
| $\sigma_n$                 | = | Nominal stress                                                                                        |
| $\theta$                   | = | Weld flank angle                                                                                      |
| $\Delta S_{\text{weld}}^A$ | = | Experimental fatigue strength under pure axial loading                                                |
| $\Delta S_{\text{weld}}^B$ | = | Experimental fatigue strength under pure bending loading                                              |

(THIS PAGE INTENTIONALLY LEFT BLANK)

## 1.0 INTRODUCTION

Cyclic loading causes fatigue cracking in a ship's welded structural details. If these details are not designed to resist fatigue cracking, the ship's profitability may be affected by repair costs and its economic life shortened. Fatigue cracks, for instance, may lead to fractures in ship's primary hull structure, an event resulting in catastrophic failure. Therefore, designers should use structural details that minimize fatigue damage and ensure structural integrity for the ship's intended service life.

One technique for predicting and assessing fatigue cracking uses empirical data derived from laboratory tests of representative structural details. After details undergo fatigue tests, test data are analyzed in terms of stress applied to each detail and the number of cycles required to reach failure. The test results are commonly referred to as S-N data and are presented in S-N curves.

The fatigue design curves presented by Munse (1) and re-analyzed by Stambaugh and Lawrence (2) are for various structural geometries that are difficult to apply to ship structural details. This report presents a fatigue design strategy to apply fatigue data to welded ship structural details. The fatigue design strategy is based on the nominal stress approach for basic welded structural configurations. A variation of the nominal stress approach is used for weld terminations in attached bracket details. After having separated the global geometric stress concentration factors from the welded details, it is possible to select weld configurations that improve fatigue life and assess the impact of geometric stress concentration factors and combined loadings typical of welded ship structural details.

The case studies used to characterize the stress in typical ship structural details are presented in Appendix A. The approach used to develop the fatigue design strategy is presented in Appendix B. A methodology for evaluating the effect of weld parameters (e.g., geometry and residual stress) is presented in Appendix C. A glossary of terms is presented in Appendix D.

## **2.0 FATIGUE IN SHIP STRUCTURAL DETAILS**

Throughout its service life, a ship experiences environmental loading which causes cyclic stress variations in structural members. Those variations can cause fatigue cracking in welded structural details if the details are inadequately designed. A fatigue assessment, supported when appropriate by fatigue analysis, should ensure that structural members do not lead to catastrophic failure. Fatigue-critical locations have been identified in a survey of standard structural details by Jordan et al. in SSC-272 (3) and SSC 294 (4). Stambaugh (5) presents fatigue-critical locations for special details that may lead to fracture. The fatigue life of a structural detail is determined by the number of cycles required to initiate a fatigue crack and propagate it from subcritical to critical size. Description of the fatigue cracking in ships has been documented by Jordan (1) and Stambaugh (3). One example of a side shell longitudinal and transverse cutout connection is shown in Figure 2-1 (6). This example is one of many that illustrate the complexity of fatigue cracking in welded ship structural details. In the example, lateral load from internal cargo and wave impact produces local loads on the side shell longitudinals. High stress concentrations are produced at the toe of welds in attached stiffeners and tripping brackets. This, combined with the use of high strength steel, (HTS) produces higher nominal stresses in the longitudinal stiffener (with little corresponding increase on fatigue strength) reduces fatigue life to five or ten years at best. Fatigue analysis should be considered for these locations and wherever special or new details are introduced in the ship's primary structure.

### **2.1 STRUCTURAL LOADING AND STRESS**

Hull loads from waves and other sources must be transformed to stress distributions in the structural detail. Because it depends on the type of ship and operational environment, predicting and analyzing fatigue stresses is complex. The designer must estimate the magnitude of the stresses and determine their impact on fatigue response.

In a ship's steel structure, stress cycles are generally caused by the seaway and by dynamic effects such as bottom slamming and hull girder whipping. Changes in cargo distribution and local loads induce bending moments. Together, all of these loads produce bending stress and shear stress in the ship's hull girder. Local stresses caused by changes in hydrostatic pressure and local loading from cargo or ballast are also superimposed on the hull girder stress. If pertinent to a particular ship, other loading from dynamic effects, stresses from thermal differences in the girder, and residual stresses should be considered in the fatigue analysis.

Global loads are distributed through plates, girders, and panel stiffeners, all of which are connected by welded structural details that may concentrate stress.

## 2.2 PREDICTING FATIGUE RESPONSE

Loading and resultant stresses are complex and random in nature. Therefore, a probabilistic approach is often used to characterize the long-term stress response distribution. The distribution is first developed by combining probabilities for each load and corresponding stress state. Then, the stress response transfer function is predicted for the individual load cases; and, finally, the distribution of joint probabilities are combined based on the probability of occurrence of each sea state.

Techniques for predicting long-term load and stress distribution and their development have been investigated extensively by Munse (1), White (7), Wirsching (8), and others but with little agreement as to the type of distribution that accounts for random load effects. The designer, therefore, must choose the dominant loads and combine them as they are expected to combine during the ship's service life. The long-term stress distribution is used in the cumulative damage analysis along with the S-N data applicable to the structural detail in question.

The cumulative damage approach is a method used to predict and assess fatigue life. As developed by Miner (14), this approach requires knowledge of structural loading and the structure's capacity expressed as stress range and number of cycles to failure. Developed from test data typically illustrated as (S-N curves), this method is based on the hypothesis that fatigue damage accumulates linearly and that damage due to any given cycle is independent of neighboring cycles. By this hypothesis, the total fatigue life under a variety of stress ranges is the weighted sum of the individual lives at constant S, as given by the S-N curves, with each being weighted according to the fractional exposure to that level of stress range. To apply this hypothesis, the long-term distribution of stress range is replaced by a stress histogram, consisting of a convenient number of constant amplitude stress range blocks,  $S_i$ , and a number of stress cycles,  $n_i$ . The constraint against fatigue fracture is then expressed in terms of a nondimensional damage ratio,  $\eta$ :

$$\sum_{i=1}^{\beta} \frac{n_i}{N_i} \leq \eta_L$$

|       |          |   |                                                               |
|-------|----------|---|---------------------------------------------------------------|
| where | $\beta$  | = | number of stress blocks                                       |
|       | $n_i$    | = | number of stress cycles in stress block i                     |
|       | $N_i$    | = | number of cycles of failure at a constant stress range. $S_i$ |
|       | $\eta_L$ | = | limit damage ratio                                            |

The limit damage ratio  $\eta_L$  depends on maintainability, that is, the possibility for inspection and repair, and the fatigue characteristics of the particular detail. These factors also have probabilistic uncertainty associated with them.

Fatigue design, using the linear cumulative damage approach, ensures the safety or performance of a system for a given period of time and/or under a "specified" loading condition. But the absolute safety of the system cannot be guaranteed because of the number of uncertainties involved. In structural design, these uncertainties can be due to the random nature of loads, simplifying assumptions in the strength analysis, material properties, etc.

### 3.0 FATIGUE DESIGN STRATEGY

A fatigue design strategy is presented to facilitate correlation between existing fatigue data and welded ship structural details. The fatigue design strategy is based on fatigue data presented by Munse (1) and re-analyzed by Stambaugh and Lawrence (2) for various structural geometries. Fatigue response data are presented to use with geometric stress concentration factors and combined loadings typical of ship structural details as developed in Appendix A and B. The fatigue design strategy is based on the nominal stress approach with modifications for induced stress concentration factors (e.g., brackets, toes and weld terminations) with various geometries. After having separated the global geometric stress concentration factors from the welded details, it is possible to select weld configurations that improve fatigue life and assess the impact of geometric stress concentration factors. A methodology for evaluating the effect of weld parameters (e.g., geometry and residual stress) is presented in Appendix C.

#### 3.1 FATIGUE DESIGN STRESS

Fatigue design stress ( $\sigma_f$ ) is defined as the stress range (double amplitude) in the location of the weld in the absence of the weld. The overall geometry of the weld need not be considered unless there are discontinuities from overfill, undercutting, or gross variations in the weld geometry. The relevant stress range must include any local bending and stress concentrations caused by the geometry of the detail as described next.

For bracketed details, combined stress from various load sources (shown in Figure 3-1) can be obtained from Finite Element Analysis (FEA). The maximum principal stress (9) should be used for combined stress fields. For deep beams and girders, bending stress is essentially an axial stress at the location of interest. This is in contrast to plate bending and associated gradients that have an effect on the fatigue life. Where out of plane stresses are high, the maximum principal stress may occur at the upper weld toe in the attachment. Thus, knowing where the maximum principal stress occurs is important and can be identified from FEA.

An illustration of global geometry and local weld toe geometry is shown in Figure 3-1. Stress associated with the physical geometry in structural details can be estimated by FEA. The stress gradients are very steep in the vicinity of the weld toe. Because of the high gradients, the maximum stress computed or measured will be sensitive to the mesh size. Because of this mesh sensitivity the fatigue design stress developed using FEA must be defined. The fatigue design stress is the principal stress on the order of one plate thicknesses from the weld toe as illustrated in Figure 3-2. Parametric approximations of stress concentration factors can be used to screen details; however, FEA should be used for fatigue critical locations. The application of the finite element technique to ship structural details is described by Liu and Bakker (10).

$$\sigma_f = \sigma_{\text{principal}} \quad \text{FROM FEA}$$

$$\sigma_f = \sigma_n \cdot K_{\text{scf}} \quad \text{FROM BEAM ANALYSIS}$$

Figure 3-2 Estimating fatigue design stress from FEA

## 3.2 FATIGUE NOTCH FACTORS

Fatigue Notch Factors ( $K_f$ ) associated with basic weld details provide a valuable tool in assessing the fatigue life of welded ship structural details because they can be used in quantitative evaluations and comparisons. Clearly, this is beneficial for application to various geometries of welded ship structural details. Baseline fatigue notch factors are developed that represent butt welds or fillet welds. In this case the effect of the local stress concentration at the weld toe is included in  $K_f$ . Therefore, the fatigue notch factor includes effects associated with weld geometry.

### 3.2.1 Definition of Fatigue Notch Factors

The basic weld configurations presented in Table 3-1 are correlated to a basic ship structural detail design curve using a fatigue notch factor  $K_f$ .

The fatigue notch factor  $K_f$  for each detail was estimated from the University of Illinois Urbana-Champaign (UIUC) fatigue data bank (2),(11) information in the following manner. At a given fatigue life, the fatigue notch factor  $K_f$  is defined as:

$$K_f = \frac{\Delta S_{\text{smooth specimen}}}{\Delta S_{\text{weldment}}} \quad (2)$$

The ratio of mean fatigue strength at  $10^6$  cycles of smooth specimen to that of plain plate is 1.43. Therefore, the  $K_f$  can be written as:

$$K_f = 1.43 \frac{\Delta S_{\text{plain plate}}}{\Delta S_{\text{weldment}}} \quad (3)$$

$$K_f = 1.43 \frac{\Delta S_{\text{plain plate}}}{\Delta S_{\text{weldment}}} \text{ at } 10^6 \text{ cycles and for } R=0 \quad (4)$$

The development of fatigue notch factors is presented in Appendix B.

|                                                                                     | Lap weld out of plane load. | 5.5   | 4.4     | $\sigma_f$ = nominal stress at $t$ away from toe of weld. Axial load induces bending.                                   |

### 3.2.2 Design Curves

The mean fatigue strength of a weldment based on its fatigue notch factor and the fatigue strength of the plan plate specimen at the fatigue life in question can be written as:

$$\Delta S_{weld} = \frac{\Delta S_{ss}}{K_{fweld}} = \frac{1.43 \Delta S_{pp}}{K_{fweld}} \quad (5)$$

Assuming that the scatter in fatigue life data can be described by the standard deviation of the log of the fatigue strength (SD), the design stress would be:

$$\Delta S_{design} = \Delta S_{weld} - 2 \cdot 10^{SD} \quad (6)$$

where:

SD = Log standard deviation of fatigue strength at  $10^6$  cycles

Thus, at  $10^6$  cycles

$$\Delta S_{design} = \frac{1.43 \Delta S_{pp}}{K_{fweld}} - 2 \cdot 10^{SD} \quad (7)$$

This relationship is illustrated in Figure 3-3.

The curves are assumed to be parallel consistent with recent work (2) and current practice in development of fatigue design curves (12, 13) for welded structural details.

The approach used to develop the  $K_f$  curves and data is discussed in Appendix A. The welded detail  $K_f$  description, loading, and pictographs are presented in Table 3-1.

The basic design curves, which consist of linear relationships between  $\log (\Delta S_R)$  and  $\log (N)$ , are based on a statistical analysis of experimental data as described by Stambaugh (2). Thus the basic design curves are of the form:

$$\log (N) = \log C - m \cdot \log (\Delta S_R)$$

Figure 3-3 Fatigue design curves developed from  $K_f$

or in terms of stress range:

$$\Delta S_R = (C/N)^{1/m}$$

where:

- N is the predicted number of cycles for failure under stress range  $\Delta S_R$
- C is a constant relating to the mean design curve
- m is the inverse slope of the design curve

The fatigue design curve shown in Figure 3-4 includes the mean minus two standard deviation adjustment. The relevant statistics are:

$$\begin{aligned}\log C &= 4.38 \\ m &= 3 \\ SD &= .0696 \text{ at } N \ 10^6 \text{ cycles}\end{aligned}$$

The slope of the design curve is bi-linear to account for the constant amplitude fatigue limit. This limit begins at  $5 \cdot 10^6$  cycles. When all nominal stress ranges are less than the constant amplitude fatigue limit for the particular detail, no fatigue assessment is required.

The design curve has a cut off limit at  $10^8$  cycles. This limit is calculated by assuming a slope corresponding to  $m=5$  below the constant amplitude fatigue limit. All stress cycles in the design spectrum below the cut off limit may be ignored when the structure is adequately protected against corrosion.

Other than as described above, no qualitative adjustments are included in this data set. Adjustments required to account for other factors influencing fatigue response are left to the designer, who should find the research described in the following sections helpful.

### 3.3 ADJUSTMENTS TO FATIGUE LIFE DATA

#### 3.3.1 Mean Stress

The correction for mean stress ratios other than  $R=0$  is based on work by Lawrence (13), who propose an equation to calculate the mean fatigue strength of weldments at long lives.

$$\frac{\Delta S_R}{\Delta S_{R=0}} = \frac{1+(2N)^b}{1+\frac{1+R}{1-R}(2N)^b} \quad (8)$$

Figure 3-4 Ship detail fatigue stress design curve

This equation is used to predict the mean fatigue strength at any R value at  $10^6$  cycles from the R=0 fatigue strength at  $10^6$  cycles. Fatigue strength exponent b is estimated by:

$$b = -\frac{1}{6} \log_2 \left( 1 + \frac{50}{1.5S_u} \right) \quad (9)$$

where  $S_u$  is the ultimate strength of base metal. The derivation of this correction is presented by Stambaugh and Lawrence (2) along with its validation using the UIUC fatigue data bank.

### 3.3.2 Corrosion

Salt water can seriously affect the fatigue life of structural details. The data available (15), (16), (17) indicate that corrosion decreases fatigue life where details are uncoated or do not have cathodic protection. When no consistent protection is provided, evidence suggests that fatigue life should be reduced by a factor of two for all categories. Corrosion also affects fatigue limit, which becomes non-existent when corrosion is present. As noted by UK DOE (18), the design curve must be continued without a change in slope.

### 3.3.3 Thickness

At present, most agree that for geometrically similar welds larger weldments will sustain shorter fatigue lives. Theoretical (19) and experimental (20) evidence confirm the existence of a size effect, but there is much scatter in the data. Thus, the magnitude of the thickness effect remains in question. Lawrence (11), Gurney (21), and Smith (22) recommend the following relationship:

$$\left[ \frac{S_1}{S_2} \right] = \left[ \frac{t_2}{t_1} \right]^m \quad (10)$$

where

- $t_2$  is taken to be 25mm (1 inch)
- $t_1$  is the thickness of plate (mm)
- $S_1$  is the design stress at the thickness in question
- $S_2$  is the design stress for the referenced thickness
- $m$  is 1/4 as recommended by Lawrence (11) for the S-N curves given by Stambaugh and Lawrence (2).

The 25mm reference thickness cited is greater than most structural details constructed of steel plate and shapes. Therefore, the correction need not be applied unless the base plate thickness is greater than 25mm.

#### **3.3.4 Fabrication**

The fabrication process is a very important factor in the fatigue life of welded structural details. Data used to develop the fatigue design strategy assume that weld quality is free of critical defects and meets the requirements of regulatory and classification societies. Joint misalignment has a significant effect on fatigue life (23),(24). Weld profile changes by grinding and peening affect fatigue response as noted in the UK DOE (18) design code. Residual stress is a very important factor especially in weld termination. Control of weld geometry and residual stress are effective means of increasing fatigue life. The analytical expressions presented in Appendix C can be used to assess the impact of weld parameter control on fatigue response. Although weld parameter control is often considered expensive, it is worth considering in special cases.

## 4.0 IMPROVED DETAILS RELATIVE TO FATIGUE

Ship structural detail design depends on many factors that are unique to the specific application. Ship type, size, loading, detail location and many other variables influence their design. However, basic parameters can guide detail designers in selection and application of structural details. These parameters include weld configuration, detail geometry and nominal stress. An understanding of these parameters and their relationship will aid in selecting, evaluating and finalizing detail design as described next.

### 4.1 DESIGN OBJECTIVE

The approach based on  $K_f$  can be used by designers to improve fatigue life of welded ship structural details. Separating geometric effects ( $K_{scf}$ ) from the fatigue notch factor ( $K_f$ ) enables ship structural designers to control variables that influenced fatigue response. The designer can determine which parameters he must control within his design constraints (cost and construction capability) when the primary objective is a constant fatigue life for a specific detail. To illustrate this point, the fatigue life ( $N$ ) based on  $K_f$  and  $K_{scf}$  can be expressed as:

$$N = f(\sigma_f, K_f)$$

where;  $\sigma_f = \sigma_n$  for simple geometries and

$$\sigma_f = \sigma_n * K_{scf} \text{ for more complex geometries (e.g. brackets)}$$

here;  $\sigma_n$  is the nominal stress and

$\sigma_f$  is the fatigue design stress one plate thickness from the weld toe.

Assuming the designer is working to a constant fatigue life, the important parameters become  $K_f$ ,  $K_{scf}$ , and  $\sigma_n$ . As a practical matter, it is very difficult to design ship structures using  $K_{scf}$  because it varies depending on application and FEA is required to determine the fatigue design stress  $\sigma_f$  for fatigue critical locations. All too often detail designers are expected to provide a detail ( $K_{scf}$ ) that will improve fatigue life; however,  $K_{scf}$  alone is insufficient and re-evaluation of the nominal stress  $\sigma_n$  is required in many instances. Nominal stress has a significant influence on fatigue life. Detail designers must assess the trade-off between these parameters because the selection of details depends on the specific application. The reliability approach developed by Munse (1) and  $K_f$  presented in Table 4-1 provide guidance in making this assessment when combined to illustrate the trade-off between  $K_f$  and  $K_{scf}$ . The following can be inferred by inspection of the information provided in Figure 4-1.

Table 4-1

Fatigue Notch Factors for  
Panel Stiffener Connections

| Ship Detail                                                                         | $K_f$ | Comments                                                                                                                                                     |
|-------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | 3.0   | Connection has high stress concentration factor and is suitable for low nominal stress applications. $K_{scf}$ of 3.3 or greater.                            |
|   | 3.0   | Connection increases area and reduces stress concentration slightly. $K_{scf}$ of 2.8.                                                                       |
|  | 3.0   | Connection area and bracket reduce stress at bracket toe. $K_{scf}$ of 2.7. Fatigue critical location depends on effective shear connection to longitudinal. |
|  | 3.0   | $K_{scf}$ of 2.3. Fatigue critical location depends on effective shear connection to longitudinal.                                                           |

Fatigue Notch Factors for  
Deep Bracket

| Ship Detail                                                                         | $K_f$ | Comments                                                                                                                                                    |
|-------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | 3.0   | Stiffener at end of bracket introduces high $K_{scf}$ . Use FEA for high stress applications.                                                               |
|   | 3.0   | Most economical means of reducing $K_{scf}$ . See Figure 4-3 for recommended proportions. Use FEA for high stress applications.                             |
|  | 3.0   | Slight increase in $K_{scf}$ . Use FEA for high stress applications.                                                                                        |
|  | 3.0   | Best configuration to reduce $K_{scf}$ at bracket toe. Also reduces stress from out of plane bending at toe. Exact geometry should be determined using FEA. |

|   | 1 - 1.7<br>2 - 3.44             | Geometry must be evaluated carefully to reduce $K_{scf}$ .                                                       |
|  | 1 - 1.7<br>2 - 3.44<br>3 - 2.62 | Effective shear connection is important in reducing nominal stress at point 3.                                   |
|  | 2.93                            | Weld wrap and quality of weld are important in tight connection.                                                 |

Table 4-1

Fatigue Notch Factors for  
Deck and Side Penetrations

| Ship Detail                                                                         | $K_f$ | Comments                                                                                                                  |
|-------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------|
|    | 1.7   |                                                                                                                           |
|   | 3.0   | Face plate introduces weld increasing $K_f$ but reduces $K_{scf}$ in detail. Weld quality is very important in this area. |
|  | 1.7   | $K_{scf}$ is very sensitive to opening size and radius. See refs. (25) and (26) for examples.                             |
|  | 3.0   | Weld quality is very important for all main deck and bottom penetrations and attachments.                                 |

Table 4-1

**Fatigue Notch Factors for  
Miscellaneous Cutouts**

| Ship Detail                                                                         | $K_f$ | Comments                                                                                                                  |
|-------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------|
|    | 3.0   | Size and number of cutouts are important relative to adjacent structure and can increase $\sigma_f$ at critical location. |
|   | 3.0   |                                                                                                                           |
|  | 3.0   |                                                                                                                           |
|  | 1.7   |                                                                                                                           |

Figure 4-1 Illustration of the relationship between  $K_f$  and  $K_{scf}$

$$K_{scf} * K_f < 4 \text{ for High Strength Steel } (\sigma_n = .3\sigma_y \text{ HS})$$

$$K_{scf} * K_f < 8 \text{ for Ordinary Strength Steel } (\sigma_n = .3\sigma_y \text{ OS})$$

While these are approximate relationships, they are useful in comparing details and evaluating the trade-off between  $K_{scf}$ ,  $K_f$ , and  $\sigma_n$ . Final determination of  $\sigma_f$  should be based on FEA and  $K_f$  presented in Table 3-1.

#### **4.1.1 Reducing Fatigue Notch Factors ( $K_f$ )**

Improvements in  $K_f$  result from changes in weld type, weld geometry, residual stress or mechanical profiling. The effects of these parameters can be significant and used as a technique to improve fatigue life. Weld profiling by grinding and peening improves  $K_f$  and extends fatigue life. These techniques are generally used selectively because of the associated increase in fabrication cost. Analytical expressions involving these parameters and effects on  $K_f$  are discussed in greater detail in Appendix C. Typical values of  $K_f$  are presented in Table 4-1 for ship structural details based on inspection of the details and application of  $K_f$  values from Table 3-1.

#### **4.1.2 Reducing Stress Concentration Factors ( $K_{scf}$ )**

Stress Concentration Factors ( $K_{scf}$ ) have an infinite number of variations. The designer can select from a number of geometries each of them having a significant effect on the fatigue design stress  $\sigma_f$ . Table 4-1 presents typical values of  $K_{scf}$  to illustrate the trade-off between  $K_f$  and  $K_{scf}$ . The  $K_f$ ,  $K_{scf}$  curves shown in Figure 4-1 can be used to screen details and aid the detail designer. Final selection of the detail should be based on FEA to determine  $\sigma_f$ .

#### **4.1.3 Reducing Nominal Stress**

Reducing nominal stress in ship structural details is an effective way to reduce fatigue design stress ( $\sigma_f$ ) and improve fatigue life.

For example, an increase in frame section modulus will reduce the stress in the detail and weld toe, assuming constant load (which might be typical in using design rules). Similarly, reduction in stiffener or frame span and spacing will reduce nominal stress. The nominal stress in the structure has a significant influence on the fatigue design stress ( $\sigma_f$ ) and fatigue response. Therefore, fatigue evaluations should be conducted early in the ship design because structural detail geometry produces stress concentrations that cannot compensate for detrimental effects of high nominal stress.

Another example is shown in Figure 4-2 for the symmetry of the flange on longitudinals. The flange symmetry has significant influence on fatigue strength. It was reported that a second generation VLCC experienced fatigue cracks in

Figure 4-2 Frame flange symmetry

asymmetric flanges after three to four years (27). There were no fatigue cracks found in a similar ship with symmetric flanges. An investigation found that the maximum stress in the asymmetric configuration is nearly 70 percent higher than in symmetric flanges. Therefore, use of symmetric Tee sections reduces a component of nominal stress and improves fatigue life.

## **4.2 RECOMMENDED PROPORTIONS**

Numerous examples are provided in Table 4-1 showing the trade-off between  $K_{scf}$  and  $K_f$  for panel stiffeners, tripping bracket connections, frame cutouts and for shell cutouts. Structural detail proportions are very important in lowering  $K_{scf}$  and  $K_f$ . Recommended proportions are shown in Figures 4-3 through 4-7 based on the analysis presented in Appendix A.

Recommended panel stiffener ends proportions are presented in Figure 4-3. Both toe and heel brackets are required to achieve a  $K_{scf}$  of less than 2.0.

Recommended deep brackets proportions used in double hull tankers are shown in Figure 4-4. The extended bracket toe radius reduces out of plane stress at the weld toe.

Recommended hatch corners and side shell cutouts proportions are shown in Figure 4-5. The exact proportions of these details depend on the specific application (25),(26).

Recommended bulb plate stiffener cutout proportions are shown in Figure 4-6. There are a large number of variations in cutout geometries and Table 4-1 shows  $K_{scf}$  for various angle cutouts based on data for standard structural arrangements (24). Additional proportions for cutouts are provided in SSC-266 (26). Generally, small radius corners should be avoided. Effective shear connections are extremely important in reducing  $K_{scf}$  in cutouts.

Recommended beam bracket proportions are shown in Figure 4-7. A common feature seen in the figures described above includes 5:1 slope on shaped flanges to reduce  $K_{scf}$ . Generally, plain brackets have lower  $K_{scf}$  than flanged brackets; however, plain brackets are more susceptible to buckling. Straight brackets are shown because they are more common than radiused brackets. Radiused brackets have much lower  $K_{scf}$  than straight brackets and are worth considering for plain brackets

Figure 4-4 Recommended proportions for deep bracket

$K_{SCF}$  VARIES DEPENDING  
ON APPLICATION. SEE  
REF 25 AND 26.

$K_{SCF} \approx 1/2$  RADIUS CORNER  
FOR SIMILAR APPLICATIONS.

$K_{SCF} \approx$  SAME AS ELLIPSE.

## HATCH CORNERS

Figure 4-5 Recommended proportions for hatch corners

Figure 4-6 Recommended proportions for frame cutout

$K_{SCF}$  VARRIES DEPENDING ON DEPTH OF BRACKET AND SUPPORTING MEMBERS. FLANGED BRACKETS HAVE HIGHER  $K_{SCF}$  THAN UNFLANGED.

## BEAM BRACKETS

Figure 4-7 Recommended proportions for beam brackets

not requiring rolled flanges. Proportions for panel stiffener connections and deep bracket may be used for radiused brackets. Recommended proportions for bracket thickness, leg length and flange size is presented by Glasfeld (26) and the Tanker Forum (28).

It is extremely important to use good fabrication practices described by Jordan (25) when using the fatigue design strategy and recommended proportions presented in this report. The depth of bracket ends ( $t < 1.5$ ) is extremely important in maintaining a  $K_f$  of 3.0.

Clearly, there are various improvements that reduce  $K_{scf}$ . The final selection of details and determination of  $\sigma_f$  must be verified by the designer using FEA for specific applications. The cost trade off must be assessed by the designer based on savings of material, labor, and shipyard resources. A guide for estimating the cost of structural details is provided by Jordan in SSC-331 (29).

#### 4.3 APPLICATION OF HIGH STRENGTH STEEL

The application of High Strength Steel (HTS) in ships must be approached carefully. Although the yield strength of HTS is greater, the fatigue strength of welded structural details is approximately the same as ordinary strength steel. When scantlings and resulting section modulus are reduced the nominal stress increases. This translates to an increase in nominal stress at the connecting details. This must be compensated by using details with reduced  $K_{scf}$ . For example, in sizing side shell longitudinal stiffeners of AH-36, the section modulus can be reduced to 72% of ordinary strength steel based on the high strength steel factor,  $Q = .72$ , by ABS (28). This produces a 40% increase in stress at the detail (assuming constant load). The geometric  $K_{scf}$  must reduce the stress by 40% to maintain constant fatigue life. By inspecting the trends in  $K_{scf}$  shown in Table 4-1, the double radius bracket is the only detail that produces more than 40% reduction in  $K_{scf}$  over straight panel stiffeners. The designer may also choose a smaller increase in nominal stress (say 20%) and compensate with a detail that reduces the  $K_{scf}$  by 20%. This trade-off depends on cost for the specific application. Figure 4-1 illustrates the trade-off between  $K_f$  and  $K_{scf}$  for ordinary and high strength steel. If  $K_f$  and  $K_{scf}$  are to the left of the respective material curve, the detail is satisfactory for the nominal stress indicated. If not, the nominal stress should be re-evaluated or detail  $K_f$  or  $K_{scf}$  changed.

**(THIS PAGE INTENTIONALLY LEFT BLANK)**

## **5.0 CONCLUSIONS AND RECOMMENDATIONS**

1. Recent advances in computer technology and development of pre-processors for finite element programs allows designers to analyze the stresses in ship structural details quickly. Variations can be evaluated and parametric analysis of detail configurations can be performed to guide the designer in assessing fatigue critical details. However, similar techniques are required to guide the designer in developing load histories quickly. The reliability approach developed by Munse (1) can be applied easily; however, its application has not been verified and calibrated for general use. Further development of this type of approach, combined with the fatigue design strategy presented here, will expedite detail design and fatigue analysis of more details requiring attention by designers.
2. The fatigue design strategy presented here should be used to re-evaluate stiffened panel design criteria in light of the fatigue notch factors and stress concentration factors for typical welded structural details. This evaluation should include the effects of high strength steel and non-linear effects of torsion in panel stiffeners.
3. The approach used to predict effects of weld parameters for weld terminations has been developed using existing data for attachments; however, the technique should be verified for combined loading and shear loading typical of terminations found in welded ship structural details. This effort should include both testing and analytical evaluations (using FEA) of the test specimens. Three dimensional effects at the weld should be evaluated both experimentally and analytically.

### Analysis of Ship Structural Details Used In Case Studies

(THIS PAGE INTENTIONALLY LEFT BLANK)

## A.1 CASE STUDY INTRODUCTION

The case studies presented below are used to illustrate the complex loading on ship structure details. Linear Finite Element Analysis (FEA) was used to determine the fatigue design stress ( $\sigma_f$ ) and resulting stress concentration factors ( $K_{scf}$ ). The principal stress is used to characterize the stress and estimate stress concentration factors as described in this report. The stresses and details shown are application dependent and are used as a guide to develop the fatigue design strategy.

The following case studies are used to evaluate stress concentration factors.

- 1) Double hull tanker frame cutout for a longitudinal and a deep bracket in a transverse frame.
- 2) Roll on-Roll off (Ro/Ro) ship side port.
- 3) Double hull barge transverse floor cutout for a longitudinal.
- 4) Small Water Plane Twin Hull (SWATH) beam bracket in the haunch area.

## A.2 CASE STUDY ANALYSIS

The first case study includes two details in a double hull tanker shown in Figures A-1 and A-2. The midship section of the double hull tanker is shown in Figure A-3. This is representative of a mid size tanker (A-1). Hull loading for the double hull tanker case study is developed following the ABS Guide For Fatigue Assessment of Tankers (A-2). The structural loading developed using this guide is calibrated to a long term stress distribution parameter. Hydrodynamic loading for similar sized tankers predicted by Bea, et al. (A-3) and Franklin (A-4) compares favorably with the pressure developed using ABS guidelines. The frame cutout and deep knee bracket are of interest because they experience fatigue failure (A-5). ABS guide recommends fatigue analysis for both details (A-2). Typical frame cutout loading is shown in Figure A-4. Detail geometry and FEA models of the hull sections frame cutout and a deep knee bracket are shown in Figures (A-5) through (A-9). Stress concentration factors are shown in Tables (A-1 and A-2) for panel stiffeners and deep brackets.

The Ro/Ro ship side port case study is of a detail common to Sealift ships being built in the United States (A-6). The Ro/Ro ship and side port are shown in Figures A-10 and A-11. The basic FEA model is shown in Figure A-12. Stress concentration factors are shown in Table A-3 for side cutouts.

The double hull barge case study is a cut out in the double bottom floor. Loading and response data are presented by Fricke (A-7). The midship section and detail are shown in Figures A-13 and A-14. Stress in this cutout is shown in A-14.

The SWATH case study is a beam bracket in the haunch area of the strut. Loading data will be based on the data published by Sikora (A-8). Improved detail will be based on the investigators knowledge of this type of detail in SWATH ships. The SWATH ship, midship section and beam bracket are shown in Figures A-15, A-16, and A-17. The basic FEA model is shown in Figure A-18. Stress concentration factors are shown in Table A-4 for typical beam brackets.

It is interesting to note that the chocked beam bracket has the lowest  $K_{scf}$  (1.57). This must be compared to the  $K_f$  to fully understand evaluate its application. The  $K_f$  for the weld between the bracket flange and beam flange is very important. The weld is loaded axially.  $K_f$  for an axially loaded fillet weld is 5.5 and  $K_f$  for an axially loaded groove weld is 2.63. Using the guidance provided in Section 4.1:

$$\text{Groove weld } K_f * K_{scf} = 1.57 * 2.63 = 4.1$$

$$\text{Fillet weld } K_f * K_{scf} = 1.57 * 5.53 = 8.63$$

Clearly, the fillet weld has a high combined  $K_f$  and  $K_{scf}$  at  $\sigma_n = .3\sigma_y$ . For a plain beam bracket:

$$\text{Fillet weld } K_f * K_{scf} = 3.0 * 2.25 = 6.75$$

The plane bracket has a higher combined  $K_f$  and  $K_{scf}$  than a groove welded flange bracket, but better than a fillet welded bracket for this application.

## B.0 FATIGUE NOTCH FACTORS

### B.1 DETAIL

Ship structural details vary in geometry and loading making it difficult to correlate them to existing data developed for structural details in published literature. In order to correlate the ship structural details geometries with test data, it is necessary to define basic weld configurations that are, to the extent practical, independent of detail geometry. The basic weld configurations associated with ship structural details can be defined as:

- 1) Weld ripple of longitudinally loaded groove or fillet welds,
- 2) Weld toes of transversely loaded groove welds,
- 3) Weld toes of transversely loaded non-local carrying fillet welds,
- 4) Weld toes of transversely loaded load carrying fillet welds and,
- 5) Weld toes of fillet weld terminations.

Each of these five basic weld configurations and associated failure location is correlated to an equivalent detail from the fatigue data presented in Tables B-1 and B-2 from SSC-318 (B-1) and SSC-369 (B-2). The  $K_t$  values for each detail are also shown in Table B-1 and summarized in Table 3-1 for the basic weld configurations.

The definition of stress and  $K_t$  associated with the basic weld configurations is the nominal stress range as documented in Section 3.0 of this report. However, stress and  $K_t$  associated weld termination common in ship details (shown in Table 4-1) requires re-evaluation to be generic in application. The weld termination associated with the straight attachment of detail 30 shown in Table B-2 is used to establish  $K_t$  of 3.6 at one plate thickness from the weld toe. FEA from the University of California Berkeley (B-3) presents  $K_t$  at various distances from the weld toe for a pair of similar attachment details as shown in Figures B-1 and B-2. A stress concentration factor can be inferred at one plate thickness from the weld toe. With this information, it is possible to estimate  $K_t$  of 3.0. This is independent of attachment geometry. Because this new  $K_t$  is independent of attachment geometry, it can be used with stress concentration factors associated with other detail geometries. This assumes that the designer has knowledge of the state of stress at one plate thickness from the weld toe. This must be obtained from FEA of the detail or from the nominal stress and an associated  $K_{scf}$  as described earlier in this report.

## Appendix C

### Analytical Fatigue Life Prediction

(THIS PAGE INTENTIONALLY LEFT BLANK)

## C.0 INFLUENCE OF WELD PARAMETERS ON FATIGUE LIFE

The use of  $K_f$  for the weld termination and other weld configuration permits relatively easy comparisons between details and associated stress concentration factors. Thus, the  $K_f$  approach for basic weld configurations includes the effects of such important factors as weld geometry, residual stress and mean stress because it is based on test data of actual welds. This assumes good welding practice which is somewhat subjective and produces much of the unaccounted for scatter in the test data. The following analytical expressions are useful to determine the impact of controlling these parameters.

### C.1 ANALYTICALLY ESTIMATING $\Delta S$ WELD

From Basquin's Law, Yung, and Lawrence (C-1) derived an expression to calculate the mean fatigue strength of weldments at long lives:

$$\Delta S_{weld} = \frac{2 (\sigma'_f - \sigma_r) (2N_l)^b}{K_{fmax}^{eff} \left[ 1 + \frac{1 + R}{1 - R} (2N_l)^b \right]} \quad (C-1)$$

where:

- $\sigma'_f$  = Fatigue strength coefficient
- $\sigma_r$  = Local (notch root) residual stress
- $b$  = Fatigue strength exponent
- $R$  = Load ratio

$$N_l = \text{Cycles to failure} \approx - \frac{1}{6} \log \left[ 2 + \frac{689.5}{Su} \right] (MPa, mm)$$

$$K_{fmax}^{eff} = \text{Effective fatigue notch factor} = (1 - X) K_{fmax}^A + X K_{fmax}^B$$

$$X = \frac{S_a^B}{S_a^T}$$

$$S_a^T = S_a^A + S_a^B$$

In the following section, we have assumed that the total fatigue life ( $N_T$ ) is equal to the initiation fatigue life ( $N_I$ ). It is expected therefore that this estimate of fatigue strength will be accurate only at long lives ( $\approx 10^7$  cycles) for which the propagation portion of the fatigue life ceases to be important.

### C.1.1 Ripple

The idea is that the fatigue notch provided by the ripple can be treated as an infinite array of semicircular notches. The weld metal properties determine the fatigue resistance and the residual stresses in the as-welded state.

Thus:

$$K_t = 1.6$$

$$K_{fmax} = 1 + \left[ \frac{K_t - 1}{2} \right] = 1.3$$

$$\sigma_r b = f( S_{uwm} )$$

$$\sigma_r = S_{yWM}$$

$$\Delta S_{weld} = \frac{2S_{uWM} - 2S_{yWM} + 689.5}{1.30} \left[ \frac{2N_f^b}{1 + \left[ \frac{1+R}{1-R} \right] 2N_f^b} \right] \quad (C-2)$$

### C.1.2 Groove Welded Butt Joint

The idea is that the residual stresses at the toe of the groove weld are controlled by the yield strength of the base metal and that crack initiation occurs in the HAZ; therefore the HAZ properties control the fatigue resistance. Thus, for the as-welded state:

$$\sigma'_f, b = f(S_{uHAZ})$$

$$\sigma_r = S_{yBM}$$

$$K_{fmax}^A = 1 + 0.0015(.27) (\tan \theta)^{0.25} S_{uHAZ} \sqrt{t} \quad (\text{MPa, mm})$$

$$K_{fmax}^B = 1 + 0.0015(0.165) (\tan \theta)^{0.167} S_{uHAZ} \sqrt{t} \quad (\text{MPa, mm})$$

$$\Delta S_{weld} = \frac{2S_{uHAZ} - 2S_{yBM} + 689.5}{K_{fmax}^{eff}} \left[ \frac{2N_f^b}{1 + \left[ \frac{1+R}{1-R} \right] 2N_f^b} \right] \quad (C-3)$$

### C.1.3 Non-Load Carrying Fillet Weld

The idea is that the residual stresses at the toe of the fillet weld are controlled by the yield strength of the base metal and that crack initiation occurs in the HAZ and therefore the HAZ properties control the fatigue resistance, that is all is as in B.2.2 above except for differences in the models for  $K_f$  which include the effect of the LOP (2c) oriented parallel to the applied stress:

$$\sigma'_f, b = f(S_{uHAZ})$$

$$\sigma_r = S_{yBM}$$

Case 1 - A model for  $K_{fmax}$  which considers the effect of LOP

$$K_{fmax}^A = 1 + 0.0015(.35)(\tan\theta)^{0.25} \left[ 1 + 1.1 \left[ \frac{c}{l} \right]^{1.65} \right] S_{uHAZ} \sqrt{t} \quad (MP_a, mm)$$

$$K_{fmax}^B = 1 + 0.0015(.21)(\tan\theta)^{0.167} S_{uHAZ} \sqrt{t} \quad (MP_a, mm)$$

Case 2 - A model for  $K_{fmax}$  which considers the effect leg length

$$K_{fmax}^A = 1 + 0.0015(.04) \sqrt{2 - \frac{1}{t}} S_{uHAZ} \sqrt{t} \quad (MP_a, mm)$$

$$\Delta S_{weld} = \frac{2S_{uHAZ} - 2S_{yBM} + 689.5}{k_{fmax}^{eff}} \left[ \frac{2N_l^b}{1 + \left[ \frac{1+R}{1-R} \right] 2N_l^b} \right] \quad (C-4)$$

#### **C.1.4 Load Carrying Fillet Weld**

The idea is that the residual stresses at the toe of the fillet weld are controlled by the yield strength of the base metal and that crack initiation occurs in the HAZ and; therefore, the HAZ properties control the fatigue resistance, that is, all is as in C.1.3 above except for differences in the models for  $K_f$  which include the effect of the LOP (c) now oriented perpendicular to the applied stress:

$$K_{fmax}^A = 1 + 0.0015(.35)(\tan\theta)^{0.25} \left[ 1 + 1.1 \left[ \frac{c}{l} \right]^{1.65} \right] S_{uHAZ} \sqrt{t} \quad (MP_a, mm)$$

$$K_{fmax}^B = 1 + 0.0015(.21)(\tan\theta)^{0.167} S_{uHAZ} \sqrt{t} \quad (MP_a, mm)$$

#### Load Carrying Fillet Weld: Root Failure

$$\sigma'_f, b = f(S_{uWM})$$

$$\sigma_r = 0$$

$$K-fmax^A = 1 + 0.0015(1.15)(\tan\theta)^{-0.2} \left[ \frac{c}{l} \right]^{0.5} S_{uWM} \sqrt{t} \quad (MP_a, mm)$$

$$K-fmax^B = 1 + \frac{1}{2} \left[ \frac{1 + 0.0098 \left[ \frac{C}{l} \right]^{0.12} S_{uWM} \sqrt{t}}{\frac{w^3}{2Ct^2} - \left[ 2\frac{c}{t} \right]^2} - 1 \right] \quad (MPa, mm)$$

$$\Delta S_{weld} = \frac{2S_{uWM} + 689.5}{K_{fmax}^{eff}} \left[ \frac{2N_l^b}{1 + \left[ \frac{1+R}{1-R} \right] 2N_l^b} \right] \quad (C-5)$$

At long lives, the likelihood of LOP failure in a weldment is increased. Increasing plate thickness (t) increases the tendency for LOP failure.

#### **C.1.5 A Fillet-Weld Termination**

For fillet weld terminations, the residual stresses at the toe at the end of the fillet weld are controlled by the yield strength of the weld metal and that crack initiation occurs in the HAZ and therefore the HAZ properties control the fatigue resistance. The models for  $K_f$  include the three dimensional effects of flow of the stress in the main plate into the weld and the attachment. This quantity is captured as a stress concentration factor of SCF which is the ratio of the stress at the location of the hypothetical strain gage a distance (t) away from the toe of the weld to the stresses

at the station of the weld toe in the absence of the weld. These results must be determined from the results of the original FEA.

$$\sigma'_{f, b} = f(\text{SuHAZ})$$

$$\sigma_r = S_{yWM}$$

$$\text{SCF} = 1.5$$

$$K_{fmax}^A = \text{SCF} * [1 + 0.0015(.35)(\tan\theta)^{0.25} \left[ 1 + 1.1 \left[ \frac{c}{l} \right]^{1.65} \right] S_{uHAZ} \sqrt{t}] \quad (\text{MPa}, \text{mm})$$

$$K_{fmax}^B = \text{SCF} * [1 + 0.0015(.21)(\tan\theta)^{0.167} S_{uHAZ} \sqrt{t}] \quad (\text{MPa}, \text{mm})$$

$$\Delta S_{weld} = \frac{3.0S_{uBM} - 1.55S_{uWM} + 689.5}{K_{fmax}^{eff}} \left[ \frac{2N_l^b}{1 + \left[ \frac{1+R}{1-R} \right] 2N_l^b} \right] \quad (\text{C-6})$$

## C.2 EFFECTS OF BENDING

Bending of attachments on plate is important because of minimal section depth. Bending of the plate causes stress gradient effects. Only one of the weld details in Table B-1 was subjected to pure bending. All others, while subjected to a nominal bending load, are of such a depth that the stress state at the fatigue initiation site is for all purposes an axial load, thus the loading is considered pseudo-axial. However, from this one example comparing SSC-318 (C-2) detail 30 with 30A shows that there can be a large difference to the fatigue response of weldment to pure axial and pure bending loading ( $\Delta S_{design} = 99.6 \text{ MPa}$ , axial,  $\Delta S_{design} = 144.3 \text{ MPa}$ , bending). This effect is captured by the analytical expressions for  $\Delta S_{weld}^1$  and as well as by the experimental database; however, there are very few pure bending entries in Table B-1 probably because the data has been restricted to  $R = 0$  loading conditions.

The analytical expressions of  $\Delta S_{\text{weld}}$  can deal with various combinations of axial and bending loads directly or provide an expression for predicting the expected mean fatigue life at a given long life using the experimental results for pure axial and pure bending loading:

$$\Delta S_{\text{weld}}^{A+B} = \frac{\Delta S_{\text{weld}}^A * \Delta S_{\text{weld}}^B}{\Delta S_{\text{weld}}^B (1 - x) + \Delta S_{\text{weld}}^A (x)} \quad (\text{C-7})$$

where:

$\Delta S_{\text{weld}}^A$  = Experimental fatigue strength under pure axial loading

$\Delta S_{\text{weld}}^B$  = Experimental fatigue strength under pure bending loading

The weld termination represents a large challenge because it cannot be dealt with adequately using a 2-D stress analysis. If the situation were axial loading, the ratio of the stress at the location of the hypothetical strain gage a distance (t) away from the toe of the weld to the nominal stresses at the station of the weld toe would be 1. However even in 2-D states of stress, local bending can cause stress gradients independent of the stress-concentrating effects of the weld toe. In situations such as the weld termination the relationship between the nominal stress at the location of the strain gage and that at the station of the weld toe is dependent upon many factors. To solve this problem the designer determines the stress at the location of the weld toe from the results of a finite element method and expressed it as an SCF. Incorporation of this SCF into the expression for  $K_t$  for the fillet weld and assuming the high level of tensile residual stresses possible because of the shrinkage of the weld metal, leading to the creation of an analytical model which predicted the behavior of the weld termination. It is believed that this process can also be used for other weld shapes having a geometry which cannot be analyzed as a simple "2-D" FEM problem.

Under pure axial loading and for normal weld toes ( $0 < 45^\circ$ ), fatigue is predicted always to occur at the root. Under pure bending loads, fatigue failure will always occur at the toe before the weld root. Note that most axially loaded welds have induced bending stresses at the weld toe due to the straightening of weld distortions under axial load. This effect induces secondary bending stresses which can easily cause the weld toe to become the failure site even under nominally axial loading conditions.

In Figure C-1 the ratio of  $\Delta S_{\text{weld}}(\text{root})/\Delta S_{\text{weld}}(\text{toe})$  is plotted against the ratio of bending stress amplitude to total stress amplitude (x). As seen in Figure C-1, when the value

Figure C-1 The predicted effect of bending stresses on the failure location for the Primitive F' - Load Carrying Fillet Weld at  $1E+07$  cycles.

of (x) exceeds about 0.3 (that is, when the ratio of bending to total stresses is above 0.35, the failure location should shift to the weld toe. Unfortunately the most effective way of improving the fatigue life of the load-carrying fillet weld failing from its root is to increase the weld penetration, that is, to reduce the value of (c). This change has a large beneficial effect upon  $\Delta S_{\text{weld}}(\text{root})$ , but also improves the performance at the weld toe so that shifting the failure location from the root to the toe requires large reductions in the value of (c). Note again that the above discussion assumes a zero value for the welding residual stresses at the weld root.

Calculations were made using the Initiation - Propagation Model to approximate the total fatigue life. The initiation life calculations was slightly altered to take into account the set-up cycle. The propagation life calculation was made using expressions for  $M_k$  (C-4).

### C.3 CALCULATIONS MADE USING THE ANALYTICAL EXPRESSIONS

Calculations were performed for hot-rolled steel under a load ratio (R) = 0. From the work of McMahon and Lawrence (C-7), the relationships between the ultimate strength of the base metal and the ultimate strength of the heat affected zone and the yield strength of the base metal (Figures C-1 and C-2) for hot-rolled steel were found to be:

$$\begin{aligned} S_{y\text{BM}} &= (5/9) * S_{u\text{BM}} \\ S_{u\text{HAZ}} &= 1.5 * S_{u\text{BM}} \end{aligned}$$

A reasonable (assumed) relationship between the ultimate strength of the weld metal and the yield strength of the weld metal was assumed to be:

$$S_{y\text{WM}} = (7/9) * S_{u\text{WM}}$$

In addition, the following values were assumed:

$$\begin{aligned} x &= 0.0 \\ \theta &= 45^\circ \\ t &= 19\text{mm} \\ S_{u\text{BM}} &= 414 \text{ MPa} \\ S_{u\text{WM}} &= 483 \text{ MPa} \\ S_{y\text{BM}} &= (5/9) * S_{u\text{BM}} = 230 \text{ MPa} \\ S_{y\text{HAZ}} &= 1.5 * S_{u\text{BM}} = 621 \text{ MPa} \\ S_{y\text{WM}} &= (7/9) * S_{u\text{WM}} = 376 \text{ MPa} \end{aligned}$$

The results are plotted in Figures C-3 through C-8 together with the mean S/N data of the local fatigue details from SSC-318 (C-2). In Figure C-3, the analytical expression for the ripple primitive underestimates life but is very reasonable and a somewhat

Figure C-2 Hardness of the heat affected zone as a function of base metal hardness.

Figure C-7 Comparison of the S-N data for ship structure details and the analytical expression for the weld Primitive F - Non-Load Carrying Fillet Weld

Figure C-8 Comparison of the S-N data for ship structure details and the analytical expression for the weld Primitive F' - Load Carrying Fillet Weld

conservative approximation. In Figure C-4, the analytical expression for the groove welded butt joint primitive is in very good agreement with the S-N data. It is especially good at very long lives when initiation dominates fatigue life and the absence of the propagation life does not make much of a difference. The analytical expressions for the non-load carrying fillet primitive are reasonable as shown in Figures C-5 through C-8. The analytical expressions for the termination primitive is also reasonable at long lives but is too conservative at shorter lives ( $N < 1E+06$ ).

The results are plotted in Figures C-9 through C-12 together with the mean S-N data of the local fatigue details from SSC-318. No calculations were made for the ripple (R) and groove weld (G) primitives because values of  $M_k$  were not available. The I-P calculations for the non-load-carrying fillet primitive are reasonable as shown in Figures C-9 and C-10. Comparing the I-P calculations with the I calculations, one can see the significant effect of propagation at shorter lives and its almost negligible effect at longer lives. In Figure C-11, the I-P calculation for the load-carrying fillet primitive is in good agreement with the S-N data. An increase in fatigue life is seen at high stresses due to the addition of the propagation life; but once again, not much of a difference is seen at long lives. The termination calculations agree with the S-N data over all the lives due to the addition of the propagation life but the estimated initiation portion of life seems to be a bit too long (un-conservative).

#### C.4 SUMMARY

The predictions of fatigue strength using the analytical expressions given for each of the primitives agree with the experimental results at long lives ( $N = 10^7$ ). Thus, the expressions are able to predict primitive behavior through are able to predict primitive behavior through a knowledge of the weldment material properties ( $S_u$ ), residual stress ( $\sigma_r$ ), loading conditions (x), plate thickness (t), and weld geometry ( $\theta$ , l, c). Finally, analytical predictions of the fatigue behavior of the primitives made using the I-P model were good at both long and short lives. Thus, it would appear that the I-P model agrees well with the experimental results but has the powerful advantage of revealing to the engineer the true importance of interconnectedness of the many fatigue variables influencing the fatigue behavior of a given primitive (weldment).

By assigning average values to the fatigue parameters reflected in the data base information for a primitive, the designer can gauge the anticipated effect on experimental S-N diagram information of substantial changes in: weldment size (t), R ratio, loading conditions (x), base metal and weld metal strength ( $S_u$ ,  $S_y$ ), weld geometry ( $\theta$ , l, c), residual stress conditions through the use of the expression below and the provided analytical expression for the appropriate primitive.

$$\Delta S_{weld} = \frac{1.43 \Delta S_{pp}}{SCF * K_{fweld}} \left[ \frac{\Delta S_{weld} \text{ calculated for current conditions}}{\Delta S_{weld} \text{ calculated for standard conditions}} \right]$$

|                                                           |                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>Cathodic protection</i></b>                         | A means of reducing corrosive attack on a metal by making it the cathode of an electrolytic cell. This can be done by applying an external direct current from a power source (impressed) or by coupling it with a more electro-positive metal (sacrificial).                                     |
| <b><i>Constant amplitude fatigue limit</i></b>            | The fatigue strength at $5 \cdot 10^6$ cycles. When all nominal stress ranges are less than the constant amplitude fatigue limit for the particular detail, no fatigue assessment is required.                                                                                                    |
| <b><i>Continuous termination</i></b>                      | Termination from continuous weld.                                                                                                                                                                                                                                                                 |
| <b><i>Cruciform or transverse load-carrying joint</i></b> | Specimen made from two lengths of plate welded, via fillet or full penetration welds, to either side of a perpendicular cross piece of the same section thickness.                                                                                                                                |
| <b><i>Cut-off limit</i></b>                               | The fatigue strength at $10^8$ cycles. This limit is calculated by assuming a slope corresponding to $m = 5$ below the constant amplitude fatigue limit. All stress cycles in the design spectrum below the cut-off limit may be ignored unless the detail is exposed to a corrosive environment. |
| <b><i>Design life</i></b>                                 | The period during which the structure is required to perform without repair.                                                                                                                                                                                                                      |
| <b><i>Detail category</i></b>                             | The designation given to a particular structural detail to indicate which of the fatigue strength curves should be used in the fatigue assessment. The category takes into consideration the local stress concentration at the detail, the stress direction, and residual stresses.               |
| <b><i>Discontinuity</i></b>                               | An absence of material causing a stress concentration. Typical discontinuities are cracks, scratches, corrosion pits, lack of penetration, slag inclusions, cold laps, porosity, and undercut.                                                                                                    |
| <b><i>Discontinuous termination</i></b>                   | Termination from intermittent weld.                                                                                                                                                                                                                                                               |

|                                     |                                                                                                                                                                                                                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>Fatigue</i></b>               | The damage of a structural part by gradual crack propagation caused by repeated stresses.                                                                                                                                                                                 |
| <b><i>Fatigue design stress</i></b> | The stress in a structural member at the location of the weld and at one plate thickness from the weld toe for weld termination typical for calculated using FEA. This stress is correlated to nominal stress range to determine fatigue life.                            |
| <b><i>Fatigue limit</i></b>         | See "cut-off" limit.                                                                                                                                                                                                                                                      |
| <b><i>Fatigue loading</i></b>       | Fatigue loading describes the relevant variable loads acting on a structure throughout the design life. The fatigue loading in ships is composed of different load cases.                                                                                                 |
| <b><i>Fatigue notch factor</i></b>  | Ratio of stress of a notched detail to stress for a plan detail at a constant fatigue life.                                                                                                                                                                               |
| <b><i>Fatigue strength</i></b>      | The stress range corresponding to a number of cycles at which failure occurs.                                                                                                                                                                                             |
| <b><i>Geometric stress</i></b>      | The stress at any point around the detail inter-section necessary to maintain the compatibility of displacements. This stress excludes local stress and depends on the nominal stress and overall geometry of the intersecting members.                                   |
| <b><i>Hot spot stress</i></b>       | The stress which controls fatigue endurance in tubular nodal joints. It can be defined experimentally or in design by the product of the nominal stress and the design hot spot stress concentration factor. This form is used primarily for offshore structural details. |
| <b><i>Load case</i></b>             | A part of the fatigue loading defined by its relative frequency of occurrence as well as its magnitude and geometrical arrangement.                                                                                                                                       |
| <b><i>Load stress</i></b>           | The stress due to the discontinuity at the weld and which is superimposed on the geometric stress.                                                                                                                                                                        |

***Nominal stress***

The detail stress remote from the intersection. This includes geometric stress at the weld toe in the absence of weld.

***Nominal stress range***

The algebraic difference between two extremes (reversals) of nominal stress. Usually, this difference is identified by stress cycle counting. Stress extremes may be determined by standard elastic analysis and applying forces and moments to the cross-sectional areas. Exceptions to this definition are details near cut-outs, man-holes, or other stress concentrations not shown in Table 3-1.

***Ripple***

Uneven weld surface.

***Weld profiling***

Process of mechanically altering weld surface geometry.

***Weld toe***

The intersection of the weld profile and parent plate.

## **Project Technical Committee Members**

The following persons were members of the committee that represented the Ship Structure Committee to the Contractor as resident subject matter experts. As such they performed technical review of the initial proposals to select the contractor, advised the contractor in cognizant matters pertaining to the contract of which the agencies were aware, and performed technical review of the work in progress and edited the final report.
